Recitation Hour (20.05.2020)

1) Data is collected on the time between arrivals of consecutive taxi's at a downtown hotel. We collect a data set of size 45 with sample mean $\bar{x}=5.0$ and sample standard deviation $s=4.0$. Assume the data follows a normal distribution

a) Find an 80% confidence interval for mean μ of X.

b) Find an 80% X^2-confidence interval for the mean μ of X.

Soln

a) Since σ is unknown we use the Studentized t-score

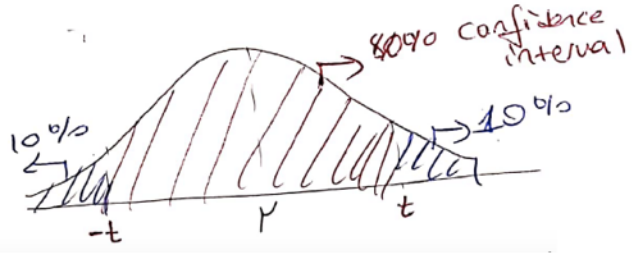
$$t = \frac{\bar{x}-\mu}{s/\sqrt{n}}$$

DF: degree of freedom

$DF = n-1$

Therefore,

$DF = n-1 = 45-1 = 44$ //



$P(X > t) = 0.1$ with 44 degree of freedom

$P(X>t) = 1 - P(X<t) = 0.1$

$P(X<t) = 0.9$

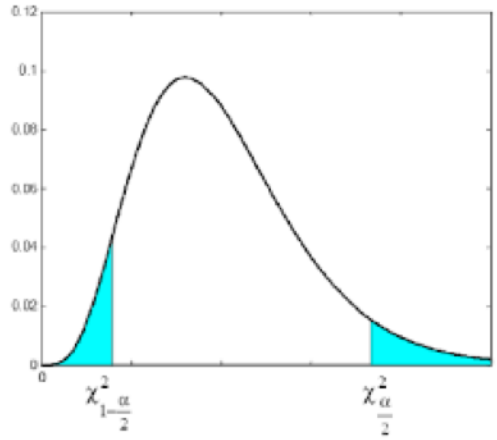
from t-table $t = 1.3$

Since, $t = \dfrac{\bar{X}-\mu}{\frac{s}{\sqrt{n}}} \Rightarrow 1.13 = \dfrac{5-\mu}{4/\sqrt{45}}$

$$\left[\bar{X} - \frac{4}{\sqrt{45}} \cdot 1.13 < \mu < \bar{X} + \frac{4}{\sqrt{45}} \cdot 1.63\right] = \text{80\% CI}$$

$5 \mp \frac{4}{\sqrt{45}} \cdot 1.13$ gives 80% CI.

b)



$$X^2 = \frac{(n-1)\,s^2}{\sigma^2}$$

→ it is not symmetric

$$X^2 = \frac{(n-1)s^2}{\sigma^2}$$

Since $\alpha = 0.2$

$P\left(X > \frac{\alpha}{2}\right)$ and $P\left(X < \frac{1-\alpha}{2}\right)$ should be determined

Therefore,

$P(X < 0.1)$ and $P(X > 0.9)$

from X^2 table for 44 degree of freedom

$P(X^2_L) = 0.9 \quad \sigma^2 = 56.37$

$P(X^2_U) = 0.1 \quad \sigma^2 = 32.49$

Therefore, $\left[\frac{(n-1)s^2}{56.37} ; \frac{(n-1)s^2}{32.49}\right] = \left[\frac{44 \times 16}{56.37} ; \frac{44 \times 16}{32.49}\right]$ achieves 80% CI

2) To test the hypothesis that eating fish makes one smarter, a random sample of 12 persons take a fish oil supplement for one year and then are given an IQ test. Here are the results:

116 111 101 120 99 106 115 107 101 110 92 94

Test using the following hypotheses for $\alpha = 0.05$

(1) $H_0: \mu = 100$
$H_1: \mu > 100$

(2) $H_0: \mu = 103$
$H_1: \mu < 103$

Find the p-value?

soln

The variance of distribution is not given and the number of samples is lower than 30 ($12 < 30$). Therefore, we can consider t-score.

From the data, the sample mean $\bar{x}$

$$\bar{x} = \frac{1}{n} \sum_{i=1}^{n} x_i = 106$$

and the sample std.

$$s_x = \sqrt{\frac{\sum_{i=1}^{n} (x_i - \bar{x})^2}{n}} = \sqrt{\frac{\sum_{i=1}^{n} (x_i - 106)^2}{12}} = 8.83.$$

Let's find t value for the first hypothesis.

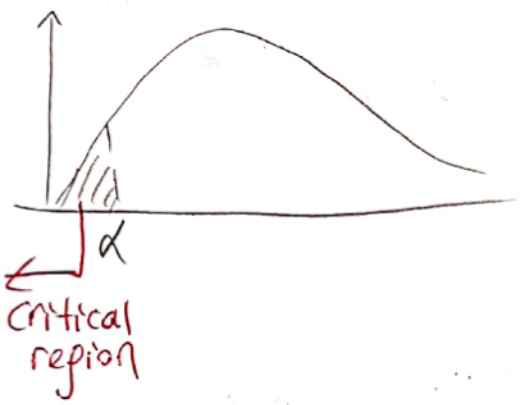
$$t = \frac{\bar{x} - \mu_0}{\frac{s_x}{\sqrt{n}}} = \frac{106 - 100}{\frac{8.83}{\sqrt{12}}} = \frac{6}{2.55} = 2.35.$$

Since $n=12$, degree of freedom (DF) for t-value is

$DF = n-1 = 11$

Therefore, from the t-table. (one tail)

$0.01 < P < 0.025$



Therefore,

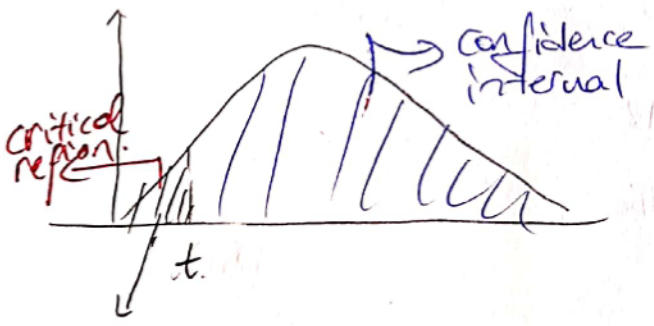
since $P < 0.05$ and in the critical region we reject H_0, and conclude that the fish oil supplement did make a significant increase in the mean IQ.

For the second hypothesis

$$t = \frac{\bar{x} - \mu_0}{s/\sqrt{n}} = \frac{106-103}{8.63/\sqrt{12}} = 1.1769 \quad \text{with} \quad DF = 11$$

Therefore, from the t-table. (one tail).

the p value is between $0.1 < p < 0.15$:



Since $0.1 < p < 0.15$ is in confidence interval.

we accept the hypothesis.
